

Project Report COMP.SE.140

Henri Rantala H293281

Instructions

To start the application, run following commands

```
$ git clone -b project https://github.com/tuniHR/DevOpsExercises.git
$ cd <created folder>
$ docker-compose build
$ docker-compose up -d
```

To start up the application locally, it is necessary that you have installed docker and docker-compose on your local machine. As per requirements, browser version can be accessed from port 8198 and API from port 8197. Note that any PUT calls through API gateway require basic auth, and as such should include -u admin:admin to authenticate the curl request.

To test the system it is possible to do with curl requests, or use the provided test script, by navigating to cloned directory and run: `bash test/test_api.sh`

Optional features

None.

Development Platform

Versions:

Docker version 27.3.1

Docker Compose version 2.31.0

Operating System: Linux (EndeavourOS), kernel: 6.12.4-arch1-1

CPU architecture: x86-64 bit

CI/CD pipeline

For version management, git was used, mainly operating only on single branch, project as there was no other contributors and work was relatively simple in scope. Thus it was more simple and easy to operate on single branch.

Docker and docker containers were used to build and deploy the system, as containers do provide easy solution for building and running systems across platforms.

For testing, simple bash scripts were used, as the test themselves were very simple API calls and checking the answers. While first test were written with python and pytest, these were translated to bash scripts to reduce number of packages and because problems with installing these packages on my local system.

Test cases:

1. GET /state without Authentication
Purpose: Check if /state is accessible without authentication.
Validation: Status code 200 and response in [INIT, PAUSED, RUNNING, SHUTDOWN].
2. PUT /state without Authentication
Purpose: Verify that state modification is restricted without authentication.
Validation: Status code 401.
3. PUT /state with Authentication
Purpose: Ensure authenticated users can change the state.
Validation: Status code 200 and response "State changed to RUNNING".
4. PUT /state to PAUSED
Purpose: Confirm state PAUSED disables /request and allow reversion to RUNNING.
Validation: Status code 200 for state changes, /request inaccessible when PAUSED.
5. GET /request
Purpose: Verify functionality of /request.
Validation: Status code 200.
6. GET /run-log
Purpose: Check /run-log reflects the current state.
Validation: Status code 200 and log includes "RUNNING".

Examples of pipeline

Example from a commit

Changes 1		Pipelines 1	
Status	Pipeline	Created by	Stages
<div>Failed</div> <div>00:00:26</div> <div>20 hours ago</div>	refine test results to print the error code #1280 project 817c1fd		<div> </div> <div> </div>

Failure in tests

Reflections

The most difficult thing during this project was setting up the actual pipeline, from setting up the runner and getting first simple build pipeline to work. This was also the greatest learning that the project provided, to learn to setup and define a pipeline. Also test driven development while not new concept for me, was something that was new in practise for me and this also gave some experience and perspective.

Hour estimate: 30h

AI/LLM usage

This project was done with assistance from ChatGPT. ChatGPT was used to help construct individual functions, small scripts, components and troubleshooting. However, some or even most results given by ChatGPT were modified or at least refined with iterative exchances with ChatGPT as initial results were often not satisfactory. While ChatGPT was not always correct, it did significantly improve and speed up development.
